

Web Hero Setup - Nazifa

Web Hero — Setup Instructions for Nazifa

This is your guide to getting the project running on your Mac and joining the team's GitHub workflow.

What you'll need

- A Mac with Terminal (already built in, no install needed)
- Homebrew (a tool installer for Mac) — if you don't have it, see Step 1
- raylib (the graphics library the game uses)

Step 1 — Install Homebrew (if you don't already have it)

Open **Terminal** and run:

```
which brew
```

If it prints a path, you already have Homebrew — skip to Step 2.

If it says nothing or "not found," install it:

```
/bin/bash -c "$(curl -fsSL  
https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"
```

Follow any on-screen instructions it gives you, including any step that asks you to add Homebrew to your PATH.

Step 2 — Install raylib

```
brew install raylib
```

Step 3 — Download the project

Pick a folder for the project (your Desktop is fine). In Terminal:

```
cd ~/Desktop  
git clone https://github.com/Anha-Khan/Weboftrails.git  
cd Weboftrails
```

Step 4 — Switch to your own branch

```
git checkout feature/nazifa
```

This is your personal workspace. You can experiment here freely without affecting Anha's or Chand's work.

Step 5 — Build and run the game

```
make run
```

A window should open with a sky-blue background, a green ground, and a colored box you can move with **A/D** (left/right) and make jump with **SPACE**.

If you see an error instead, copy the exact text of the error and send it to Anha, or paste it into Claude — don't try to guess your way through it. Setup errors are normal on a first try.

| Step 6 — Read the team workflow guide

Before changing or adding anything, open the file `CONTRIBUTING.md` inside the project folder. It explains:

- How we use git as a team without overwriting each other's work
- The exact commands for saving and sharing your progress
- Common mistakes and how to avoid them

It's short. Read it once before your first commit.

| Quick glossary

- **Repo** — short for "repository," the whole project folder as it exists on GitHub.
- **Clone** — downloading a copy of the repo onto your own computer.
- **Branch** — your own personal workspace inside the project.
- **Commit** — saving a snapshot of your changes.
- **Push** — uploading your saved changes to GitHub.
- **Pull** — downloading other people's changes onto your computer.

If anything doesn't make sense, ask. There's no such thing as a dumb question — everyone on this team is still learning this.
